

# **AI Assisted Coding**

## **Assignment - 02**

**Name : B.Sai Varsha**

**Roll No : 2303A54065**

**Batch : 48**

### **Lab 2: Exploring Additional AI Coding Tools beyond Copilot – Gemini (Colab) and Cursor AI**

#### **Task 1: Statistical Summary for Survey Data**

- ❖ **Scenario:** You are a data analyst intern working with survey responses stored as numerical lists.
  - **Prompt used :**  
"Write a Python function that takes a list of numbers and returns the mean, minimum, and maximum values."
  - **Generated code :**

```
import statistics
def analyze_numbers(numbers):
    """
    Calculates the mean, minimum, and maximum of a list of numbers.

    Args:
        numbers (list): A list of numerical values.

    Returns:
        tuple: A tuple containing (mean, minimum, maximum).
        Returns (None, None, None) if the list is empty.
    """
    if not numbers:
        return None, None, None
    mean_value = statistics.mean(numbers)
    min_value = min(numbers)
    max_value = max(numbers)
    return mean_value, min_value, max_value
```

#### **Example Usage**

```
data = [10, 20, 30, 40, 50]
mean, minimum, maximum = analyze_numbers(data)
print(f>List: {data}")
print(f"Mean: {mean}")
print(f"Minimum: {minimum}")
print(f"Maximum: {maximum}")
```

```

data_empty = []
mean_empty, min_empty, max_empty = analyze_numbers(data_empty)
print(f"\nList: {data_empty}")
print(f"Mean: {mean_empty}")
print(f"Minimum: {min_empty}")
print(f"Maximum: {max_empty}")

```

- **Sample Output :**

List: [10, 20, 30, 40, 50] Mean: 30 Minimum: 10 Maximum: 50

List: [] Mean: None Minimum: None Maximum: None

- **Short Explanation of Logic :**

The **mean** represents the average of a set of numbers. It is obtained by adding all the values in the list and dividing the sum by the total number of elements.

The **minimum value** is the smallest number present in the list, and the **maximum value** is the largest number present in the list. These values are calculated using Python's built-in `min()` and `max()` functions.

The function accepts a list of numerical values as input, computes the mean, minimum, and maximum values, and displays them as a statistical summary of the given data.

```

import statistics

def analyze_numbers(numbers):
    """
    Calculates the mean, minimum, and maximum of a list of numbers.

    Args:
        numbers (list): A list of numerical values.

    Returns:
        tuple: A tuple containing (mean, minimum, maximum).
               Returns (None, None, None) if the list is empty.
    """
    if not numbers:
        return None, None, None

    mean_value = statistics.mean(numbers)
    min_value = min(numbers)
    max_value = max(numbers)

    return mean_value, min_value, max_value

```

**Example Usage**

```

data = [10, 20, 30, 40, 50]
mean, minimum, maximum = analyze_numbers(data)

print("List: ", data)
print("Mean: ", mean)
print("Minimum: ", minimum)
print("Maximum: ", maximum)

data_empty = []
mean_empty, min_empty, max_empty = analyze_numbers(data_empty)
print("\nList: ", data_empty)
print("Mean: ", mean_empty)
print("Minimum: ", min_empty)
print("Maximum: ", max_empty)

```

**Gemini 2.5 Flash**

Write a Python function that takes a list of numbers and returns the mean, minimum, and maximum values.

Certainly! Here's a Python function that takes a list of numbers and returns its mean, minimum, and maximum values. I've also included an example of how to use it.

Explain the analyze\_numbers function. Call the analyze\_numbers function with sample data.

What can I help you build?

## Task 2: Armstrong Number – AI Comparison

- ❖ **Scenario : You are evaluating AI tools for numeric validation logic.**

- **Prompt used (Gemini):**

"Write a Python program to check whether a given number is an Armstrong number."

- **Prompt used (Copilot):**

"Write a Python program to check whether a given number is an Armstrong number."

- **Generated code (Gemini):**

```
def is_armstrong_number(number):
    """
```

Checks if a given number is an Armstrong number.

An Armstrong number (also known as a narcissistic number,

pluperfect digital invariant, or plus perfect number)

is a number that is the sum of its own digits each raised

to the power of the number of digits.

rgs:

number (int): The integer to check.

Returns:

bool: True if the number is an Armstrong number, False otherwise.

```
"""
```

```
if not isinstance(number, int) or number < 0:
```

```
    return False
```

```
    num_str = str(number)
```

```
    n = len(num_str)
```

```
    sum_of_powers = 0
```

```
    for digit_char in num_str:
```

```
        digit = int(digit_char)
```

```
        sum_of_powers += digit ** n
```

```
    return sum_of_powers == number
```

- **Generated code (Copilot):**

```
#!/usr/bin/env python3
"""Armstrong number checker (task2).

Usage:
python3 task2.py 153
python3 task2.py # prompts for input
"""

import argparse
import sys

def is_armstrong(n: int) -> bool:
    if n < 0:
        return False
    digits = [int(d) for d in str(n)]
    p = len(digits)
    return sum(d ** p for d in digits) == n

def main() -> None:
    parser = argparse.ArgumentParser(description='Check Armstrong numbers')
    parser.add_argument('number', nargs='?', type=int, help='integer to check')
    args = parser.parse_args()
```

```

if args.number is None:
    try:
        s = input('Enter a non-negative integer: ').strip()
        num = int(s)
    except (EOFError, ValueError):
        print('Invalid input', file=sys.stderr)
        sys.exit(1)
    else:
        num = args.number

    if is_armstrong(num):
        print(f'{num} is an Armstrong number.')
    else:
        print(f'{num} is not an Armstrong number.')

if __name__ == '__main__':
    main()

```

- **Sample Input (Gemini):**

```

# Test with some numbers
print(f'Is 153 an Armstrong number? {is_armstrong_number(153)}') # Expected: True
(1^3 + 5^3 + 3^3 = 1 + 125 + 27 = 153)
print(f'Is 9474 an Armstrong number? {is_armstrong_number(9474)}') # Expected:
True (9^4 + 4^4 + 7^4 + 4^4 = 6561 + 256 + 2401 + 256 = 9474)
print(f'Is 9 an Armstrong number? {is_armstrong_number(9)}') # Expected: True (9^1
= 9)
print(f'Is 10 an Armstrong number? {is_armstrong_number(10)}') # Expected: False
(1^2 + 0^2 = 1 != 10)
print(f'Is 123 an Armstrong number? {is_armstrong_number(123)}') # Expected:
False

```

- **Sample Input (Copilot):**

Enter a non-negative integer: 343

- **Sample Output (Gemini):**

```

Is 153 an Armstrong number? True
Is 9474 an Armstrong number? True
Is 9 an Armstrong number? True
Is 10 an Armstrong number? False
Is 123 an Armstrong number? False

```

- **Sample Output (Copilot):**

343 is not an Armstrong number.

- **Side-by-Side Comparison Table :**

Feature	Google Gemini	GitHub Copilot
Code structure	Uses a separate function	Written directly in main logic
Readability	Very clear and modular	Simple and straightforward
Logic clarity	Easy to understand with function	Easy but less modular
Beginner friendly	High	Medium
Explanation support	Provides explanation along with code	No explanation, only code
Best use case	Learning and documentation	Fast coding inside editor

- **Side-by-Side Comparison Table :**

**Analysis :** Google Gemini generated a well-structured and modular solution using a function, making it suitable for learning and reuse. GitHub Copilot produced a concise and direct implementation, which is efficient for quick development within an IDE. Both tools correctly implemented the Armstrong number logic, but Gemini provided better clarity and explanation, while Copilot focused on speed and simplicity.

**Conclusion :** Both AI tools effectively generated correct Armstrong number checking programs. Google Gemini is more helpful for understanding and learning due to its explanations, while GitHub Copilot is ideal for rapid code generation during development.

The screenshot shows a Google Colab notebook titled "AI\_LAB2.ipynb". On the left, the code cell contains a function definition for checking Armstrong numbers:

```

def is_armstrong_number(number):
    """
    Checks if a given number is an Armstrong number.

    An Armstrong number (also known as a narcissistic number, pluperfect digital invariant, or pure perfect number) is a number that is the sum of its own digits each raised to the power of the number of digits.

    Args:
        number (int): The integer to check.

    Returns:
        bool: True if the number is an Armstrong number, False otherwise.
    """
    if not isinstance(number, int) or number < 0:
        return False

    num_str = str(number)
    n = len(num_str)
    sum_of_powers = 0

    for digit_char in num_str:
        digit = int(digit_char)
        sum_of_powers += digit ** n

    return sum_of_powers == number

```

Below the code cell, there is an "Example Usage" section with test cases:

```

# Test with some numbers
print("Is 153 an Armstrong number? ", is_armstrong_number(153)) # Expected: True (1^3 + 5^3 + 3^3 = 1 + 125 + 27 = 153)
print("Is 9474 an Armstrong number? ", is_armstrong_number(9474)) # Expected: True (9^4 + 4^4 + 7^4 + 4^4 = 6561 + 256 + 2401 + 256 = 9474)
print("Is 9 an Armstrong number? ", is_armstrong_number(9)) # Expected: True (9^1 = 9)
print("Is 10 an Armstrong number? ", is_armstrong_number(10)) # Expected: False (9^1 + 0^1 = 9)
print("Is 123 an Armstrong number? ", is_armstrong_number(123)) # Expected: False

```

On the right side of the screen, there is a sidebar for Gemini. It shows a query and a response:

Query: "Write a Python program to check whether a number is an Armstrong number."

Response: "Okay, here's a Python program that defines a function to check if a number is an Armstrong number, along with some example usage."

The screenshot shows the VS Code interface with the following details:

- EXPLORER**: Shows a folder named "LAB2.1" containing "armstrong.py" and "task2.py".
- CODE**: The "task2.py" file is open, displaying Python code for an Armstrong number checker.
- TERMINAL**: The terminal shows the command `python3 task2.py 153` being run, followed by the output "153" and "123".
- CHAT**: A message from "PYTHON ARMSTRONG NUMBER CHECKER IMP..." says "sisted\_lab/lab2.1/armstrong.py 123". Below it, a todo item asks "Write a Python program to check whether a number is an Armstrong number." and a note says "I'll add + task2.py with the Armstrong checker, run three example checks, then update the todo list."
- STATUS BAR**: Shows the file is 43 lines long, the current line is Ln 42, and the column is Col 11. It also shows "Spaces: 4", "UTF-8", "LF", "Python", and "3.9.6".

### Task 3: Leap Year Validation Using Cursor AI

#### ❖ Scenario : You are validating a calendar module for a backend system.

- **Prompt 1:**

"Write a Python program to check whether a given year is a leap year."

- **Generated code :**

```
year = int(input("Enter a year: "))
# A year is a leap year if:
# - It is divisible by 4 AND
# - not divisible by 100, UNLESS
# - it is also divisible by 400
if(year % 4 == 0 and year % 100 != 0) or (year % 400 == 0):
    print(f"{year} is a leap year.")
else:
    print(f"{year} is not a leap year.")
```

- **Prompt 2 :**

"Write an optimized Python program with proper conditions and comments to check whether a year is a leap year."

- **Generated code :**

```
year = int(input("Enter a year: "))

# A year is a leap year if:
# 1. It is divisible by 400 → leap year
# 2. Else if it is divisible by 100 → not a leap year
# 3. Else if it is divisible by 4 → leap year
# 4. Otherwise → not a leap year
```

```

if year % 400 == 0:
    print(f"{year} is a leap year.")
elif year % 100 == 0:
    print(f"{year} is not a leap year.")
elif year % 4 == 0:
    print(f"{year} is a leap year.")
else:
    print(f"{year} is not a leap year.")

```

- **Sample Input :**

Enter a year: 2026

- **Sample Output :**

2026 is not a leap year.

- **Short Explanation of Logic :**

The first version of the code generated by Cursor AI provided basic leap year validation logic. The second prompt resulted in improved code with better readability and clear comments explaining the conditions. The optimized version is easier to understand and more suitable for real-world applications.

The screenshot shows the VS Code interface with the following details:

- File Explorer:** Shows two files: `leapyear.py` and `leapyear.py > ...`. The main file contains the Python code for checking leap years.
- Code Editor:** Displays the Python code for leap year validation.
- Terminal:** Shows the command `python3 /Users/anumandlarithika/SRU/AI_Alisted_lab/lab2.1/leap_year.py/lepyear.py` and the output "Enter a year: 2026".
- AI Interface:** A sidebar titled "Python program for leap year che..." with the instruction "Write a Python program to check whether year is a leap year." Below it, a "Plan" section shows the generated code.
- Status Bar:** Shows the cursor tab, file name, line number (Ln 10), column number (Col 41), spaces (Spaces: 4), encoding (UTF-8), and Python version (3.9.6 64-bit).

```

leapyear.py
-----
1 # Program to check if a given year is a leap year
2
3 year = int(input("Enter a year: "))
4
5 # A year is a leap year if:
6 # 1. It is divisible by 400           - leap year
7 # 2. Else if it is divisible by 100  - not a leap year
8 # 3. Else if it is divisible by 4   - leap year
9 # 4. Otherwise                      - not a leap year
10
11 if year % 400 == 0:
12     print(f"{year} is a leap year.")
13 elif year % 100 == 0:
14     print(f"{year} is not a leap year.")
15 elif year % 4 == 0:
16     print(f"{year} is a leap year.")
17 else:
18     print(f"{year} is not a leap year.")

## Task 4: Student Logic + AI Refactoring (Odd/Even Sum)

### ❖ Scenario : Company policy requires developers to write logic before using AI.

- **Prompt used :**

"Refactor this Python code to improve readability and efficiency."

- **Student Code:**

$$T = (1, 2, 3, 4, 5, 6, 7)$$

```
even_sum = 0
```

```
odd_sum = 0
```

```
for i in t:
```

```
    if i % 2 == 0:
```

```
        even_sum = even_sum + i
```

```
    else:
```

```
        odd_sum = odd_sum + i
```

```
print("Sum of even numbers:", even_sum)
```

```
print("Sum of odd numbers:", odd_sum)
```

- **AI Code:**

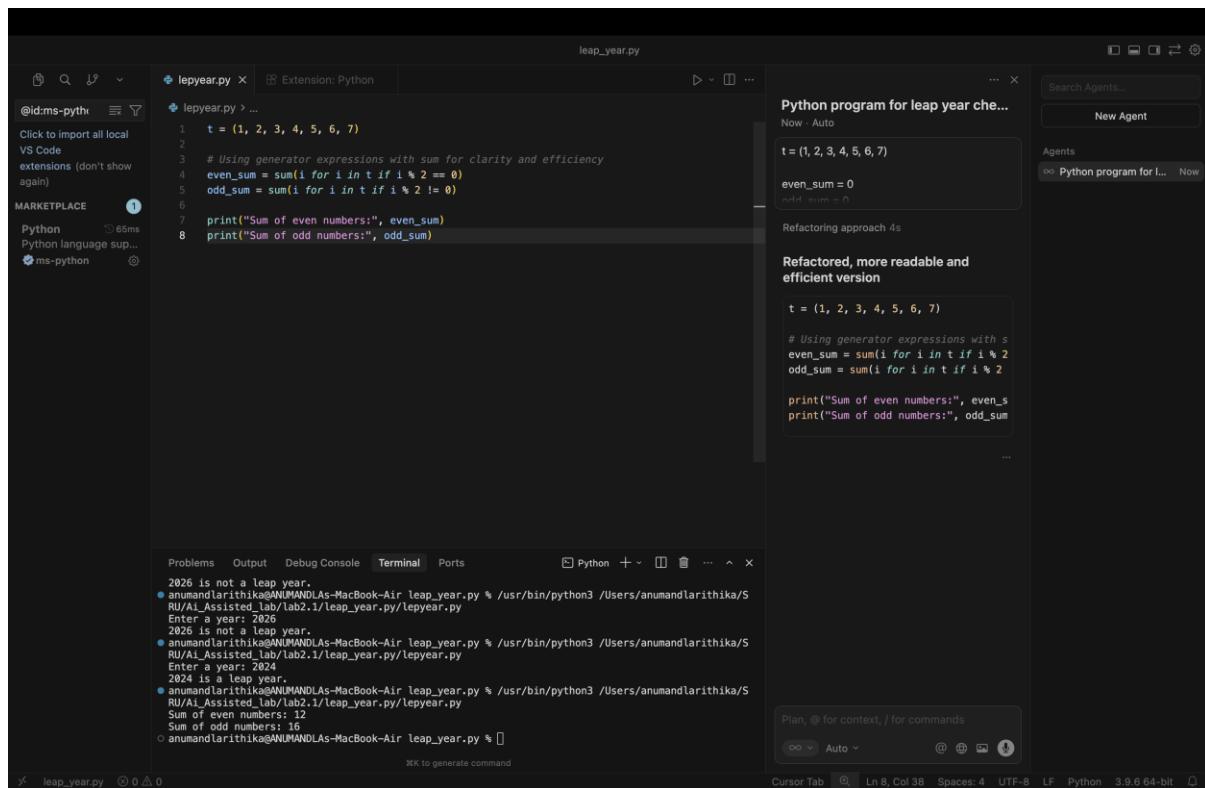

```
t = (1, 2, 3, 4, 5, 6, 7)

# Using generator expressions with sum for clarity and efficiency
even_sum = sum(i for i in t if i % 2 == 0)
odd_sum = sum(i for i in t if i % 2 != 0)

print("Sum of even numbers:", even_sum)
print("Sum of odd numbers:", odd_sum)
```

- **Sample Output :**

Sum of even numbers: 12  
 Sum of odd numbers: 16

The screenshot shows the VS Code interface with two panes. The left pane displays the original Python code for calculating the sum of even and odd numbers from a tuple `t`. The right pane shows a refactored version of the same code using generator expressions and the `sum` function. Both panes include a terminal at the bottom showing the execution of the script and its output.

```
t = (1, 2, 3, 4, 5, 6, 7)

# Using generator expressions with sum for clarity and efficiency
even_sum = sum(i for i in t if i % 2 == 0)
odd_sum = sum(i for i in t if i % 2 != 0)

print("Sum of even numbers:", even_sum)
print("Sum of odd numbers:", odd_sum)
```

**Python program for leap year check**

```
t = (1, 2, 3, 4, 5, 6, 7)

# Using generator expressions with sum for clarity and efficiency
even_sum = sum(i for i in t if i % 2 == 0)
odd_sum = sum(i for i in t if i % 2 != 0)

print("Sum of even numbers:", even_sum)
print("Sum of odd numbers:", odd_sum)
```

Refactored, more readable and efficient version

```
t = (1, 2, 3, 4, 5, 6, 7)

# Using generator expressions with sum for clarity and efficiency
even_sum = sum(i for i in t if i % 2 == 0)
odd_sum = sum(i for i in t if i % 2 != 0)

print("Sum of even numbers:", even_sum)
print("Sum of odd numbers:", odd_sum)
```
